Individuals with mild cognitive impairment (MCI) experience memory difficulties that are not severe enough to meet the criteria for a diagnosis of dementia, yet in most cases do lead to a diagnosis of mild dementia. Individuals with MCI are at greater risk of developing dementia than those without MCI, which is the group of individuals that most commonly has a learning disability (LD) in the UK. Therefore, children with MCI are likely to come from a diverse range of backgrounds, and there may be age-related differences in how they are perceived by other children in the classroom. This study explored possible age-related differences in peer reactions to the diagnosis of LD and MCI in school-age children. The participants included 25 children with MCI, 20 children with LD, and 28 children with no LD (control group). All children were matched by age and gender to one group of children with LD. Each participant completed a questionnaire on an individual basis about their peer reactions to the diagnosis of LD and MCI. A repeated measures ANOVA showed that the children in the LD group reported lower peer-rated confidence in their memory than both the children with MCI and controls, even when controlling for self-rated memory confidence. No other differences between the groups were found. It is possible that the prevalence of LDs in the UK, which is associated with a higher risk of developing dementia, may explain the reduced self-esteem that is reported by children with LD. Alternatively, this may be related to the impact of educational interventions for LD. This study indicates that self-esteem, but not peer-rated confidence, was found to be lower in the LD group, and the findings point to a potential area for intervention.Mechanisms of aldose reductase inhibition by short chain alcohols. Mechanisms of aldose reductase inhibition by short chain alcohols were examined. Inhibitor kinetic studies with purified rat lens aldose reductase showed that long chain alcohols of C7 to C11 produced linear competitive kinetics and short chain alcohols, from C3 to C5, produced inhibition that was not competitive with substrate. Short chain alcohols stimulated the oxidation of glucose and sorbitol catalyzed by purified yeast aldose reductase 2d92ce491b
