Photoionization of nitrogen in N₂/O₂/Ar gas mixtures: an ab initio study. The gas-phase photoionization of nitrogen in N₂/O₂/Ar mixtures is studied by employing the adiabatic complete-active-space self-consistent-field coupled with the time-dependent local density functional theory (TD-CAS-SCF/TD-TD-LDFT) and multireference configuration-interaction (MRCI) methods. The ground-state optimized geometries, vertical and adiabatic ionization energies, and harmonic vibrational frequencies of the ground state and the first 23 excited states of the N₂ molecule are calculated at the complete basis set limit. Single-point energy calculations are then carried out at the CCSD(T)-F12b/6-311+G** and CCSD(T)-CBS levels of theory for the optimized geometries, ionization energies, and harmonic vibrational frequencies. By taking into account the self-energy contributions, all of the single-point energy calculations are performed at the CCSD(T)-F12b/6-311+G** and CCSD(T)-CBS levels of theory. Relativistic effects are included by employing the small-core Hartree-Fock pseudopotentials. The adiabatic ionization energy of the N₂ molecule is found to be 11.23 eV, and the dissociation energy of the N₂ + O₂ radical pair is calculated to be 10.89 eV. The ground state potential energy surface is then explored with the multireference multistate second-order perturbation theory,
