The embodiments of the present disclosure are directed to a brushless direct current (BLDC) motor, and more particularly to a dual stator structure with improved flux concentration. In the prior art, a conventional BLDC motor mainly includes a stator, a rotor, and a shaft. The stator has an iron core and coils, and a stator core of the iron core is made of a plurality of teeth extending from a center of a stator core in a radial direction. The teeth are arranged along an inner periphery of the stator core and a plurality of air gap regions are defined between adjacent teeth. Each air gap region is formed by a plurality of tooth sections, and one end of the air gap region extends to a root of the tooth and the other end of the air gap region extends to an end of the stator core. A coil winding is wound on the stator core. The rotor has a plurality of permanent magnets and the stator is fixedly mounted on the shaft. A magnetomotive force of the permanent magnet is generated by the coil winding wound on the stator core, and the magnetomotive force drives the shaft to rotate. In operation of the BLDC motor, magnetic fluxes generated by the permanent magnets pass through the air gap regions of the stator core to generate a magnetic field, so that the stator core of the motor is set in a rotating state. However, in the conventional BLDC motor, magnetic fluxes generated by the permanent magnets is not concentrated on the stator core, and thus the magnetic field is not concentrated on the teeth, so that a magnetic field is not formed in the air gap regions, and thus the magnetic field is not concentrated on the stator core, and the magnetic field is not concentrated on the teeth, and thus the magnetic field is not concentrated on the stator core, and the magnetic field is not concentrated on the teeth, so that the magnetic field is not concentrated on the stator core, and the magnetic field is not concentrated on the teeth, and thus the stator core is not rotated. As a result, performance of the 70238732e0
