Freedom from in-hospital death following improved patient safety. In-hospital death is a controversial outcome in assessing hospital care quality. We sought to estimate the unadjusted and adjusted risk of in-hospital death after controlling for patient and hospital characteristics using a large cohort of Medicare beneficiaries. Using an observational cohort design, we examined the risk of in-hospital death after 1 year following the occurrence of a serious adverse event and compared the risk of in-hospital death between patients who had an in-hospital adverse event and those who did not. Using Medicare data from July 1, 2000, to June 30, 2005, we identified in-hospital serious adverse events and used multivariable regression models to examine the risk of in-hospital death in those experiencing the adverse events and in those who did not. We observed 28,788 in-hospital serious adverse events resulting in in-hospital death in 70,496 Medicare beneficiaries. After multivariable adjustment, the risk of in-hospital death within 1 year of the adverse event was 0.52 (95% confidence interval [CI], 0.51 to 0.52) times lower in beneficiaries who experienced an in-hospital adverse event compared with those who did not. After further adjustment for patient characteristics and hospital characteristics, the risk of in-hospital death after an in-hospital adverse event was 0.82 (95% CI, 0.81 to 0.82) times lower than the risk of in-hospital death for those not experiencing an in-hospital adverse event. We observed a strong beneficial effect of improved patient safety on reducing in-hospital death following the occurrence of a serious adverse event. This result was achieved despite adjustment for numerous patient and hospital characteristics, and limitations of the data do not allow us to conclude that patients at low risk of death are affected by the improvement. Our finding underscores the value of evaluating in-hospital outcomes following a serious adverse event.1. Field of the Invention The present invention relates to a physical quantity detection sensor for detecting the physical quantity associated with the combustion of an internal combustion engine, including a case member which is a hollow member formed of a metal, and an element body which is disposed within the case member and deforms based on the physical quantity, and the present invention also
