References External links Official Site of Esko Graphics Category:Office software Category:Raster graphics editors With the advent of wire bonding machines, individual conductive wires were first used to electrically interconnect the pads of electronic components and the lead fingers of packages in which the components were ultimately to be encapsulated and to effect electrical connection between the various lead connections. Later, a wire-bonding fixture, consisting of a base plate and a cap plate, was developed. This fixture was used in conjunction with a bonding tool which was used to both shape and cut the conductive wire adjacent to the bond-receiving pad, as well as to pierce the insulative sheathing and assure contact of the wire with the bare conductive core. More recently, ultrasonic bonding machines were developed which not only form the bond, but also cut the wire to the desired length. In such machines, a capillary of a tool is brought into a desired position above a selected pad on a substrate, and energized by an ultrasonic transducer such as a horn. The capillary is then vibrated vertically in a high-frequency "quacking" mode, and the capillary and wire are pressed against the pad by the transducer to form the bond. The capillary must be guided and positioned accurately. If it is not, as the capillary is moved along its path of travel to a selected pad, there may be bending of the capillary at its critical bend points, or it may be deflected to one side or the other by a projecting edge of the pad in the path of the capillary. Either condition may result in a defective bond. In one bonding apparatus, the tool includes a housing through which the bond-receiving pads extend, and two spaced rings of ultrasonic vibration transducers are located along the length of the housing, one on each side of the pad-receiving path. The transducers are connected to a power source and an electronic drive means for energizing them at precisely the same time. The apparatus is subject to the same problems as the apparatus shown in U.S. Pat. No. 4,093,926, discussed below. The present invention is directed to a wire-bonding apparatus of the type wherein the wire
