(MMI) has released a new version of their software, CamBam, specifically designed for the Rival, XP, and NX milling machines. CamBam is a CNC program that will convert a source CAD file or internal geometry editor into a gcode file and send it to your milling machine as its own stand alone program. The software was originally released in 2004 but has since gone to a paid version that includes new features and out of the box functionality. Another paid feature is the ability to convert your own internal geometry in any format to gcode. While the paid version is called the full version it only offers this ability once you have registered and paid for the software. What makes CamBam stand out from the rest is the ability to convert your own geometry to a gcode file. Most companies who mill CNC parts have already invested in a CNC controller and the most basic milling machine is controlled by an operator, the controller allows you to enter commands on your computer, sending them to the milling machine, and then watch as the machine turns those commands into metal with a single tap of a button. With CamBam you can turn that same data into gcode that your milling machine will follow. CamBam works in conjunction with your drawing software to create your shape. CamBam will take a.step or.stl file and create its gcode based on that file. The easy part is choosing your material and the software will create the path for the milling machine to follow. The more complicated part is creating the gcode path in your CAD program from there on out. CamBam's interface
