Many of the approaches, although successful in their particular function, fail to provide an integrated, high throughput, energy efficient, and economical solution. One approach utilizes a controlled burning combustion chamber, having a flame spreader which is an integral part of the burner shell. The flame spreader includes a number of radially-extending louvers. The louvers are formed to have a thin, flat, or almost flat upper surface and a conical lower surface. They are also arranged in a predetermined pattern. Another approach utilizes a smoke-producing mechanism which generates a source of smoke. The smoke-producing mechanism utilizes a blowing arrangement which includes a series of blowing vanes arranged in a circular pattern. The blowing vanes are moved inwardly to close the combustion chamber and

outwardly to open the combustion chamber. The blowing vanes are also formed in a predetermined pattern. In the past, attempts to burn gas fuel, such as methane, for a heat source have focused on the use of low-temperature heat exchangers a1d647c40b
