Our company is currently working on a database project where we have a single project and multiple client specific projects. We want the developers working with the client specific projects to be able to extract the files and change them to their relevant code. At the moment we have this: Root Project Client 1 *client1.dproj* Client 2 *client2.dproj* It means that each client has its own independent dbproj file (we are currently using Visual Studio 2008) Is there a better method to do this? We would like to have a flexible system where it is possible to extract the files and make changes to them without having to manually copy and rename files. This needs to be done for each project. A: We are currently using Git. It's quite easy to manage version changes. It's a lot like SVN which is not a bad thing for someone used to this. We haven't yet had to make any special changes on our database project though, so it's been a good solution so far.

The influence of cimetidine on the plasma glucose and insulin response to a standard oral glucose load was investigated in 10 healthy male subjects. These subjects were then allocated to either placebo or cimetidine on alternate days and crossed over to the alternate treatment during a period of 2 weeks. The fasting plasma glucose and immunoreactive insulin concentrations were not significantly affected by either treatment. However, cimetidine caused a reduction in both the peak plasma glucose and the area under the plasma glucose curve in the oral glucose tolerance test. The 2 h plasma insulin concentration was also significantly reduced by cimetidine. The results of these studies suggested that cimetidine is a hypoglycaemic agent. However, the reduction in the observed hypoglycaemia was approximately 6% of the reported glycaemic response to cimetidine. Read Time: Scientists at the University of Leeds have discovered that within a few generations, only two of the most aggressive salmonids will be able to reproduce. This means that whilst we may be able to prevent the decline of less tolerant stocks by using feed supplements, we may not be able to prevent a collapse of a wild salmon population. In a new paper published in the journal Evolutionary Applications, the researchers from the University's Biodiversity and Climate Research Centre (BiCCRC) have shown that within only four to five generations, there is a switch in the behaviour of salmonids – within a few generations, the most aggressive individuals will predominate – making them more efficient and competitive, whether naturally or through man-made interventions. The authors of the paper say that the findings have implications for conservation strategies in wild populations. “Whilst we may be able to reverse some of the losses by controlling diet, at some point you run out of time.” said Dr Giada D’Amato, Research Fellow with BiCCRC, who was lead author of the paper. “Even if we feed these salmon at levels that will counteract the natural diet that they would have experienced in the wild, over time it still takes several generations for salmonids to grow to a size that would allow them to 0298e982ba
