Immediate Access is a tool designed to monitor and report on a machine's ongoing activity on a corporate network. The main aim is to detect if a machine has fallen off a corporate network, be it an Internet-only machine, or a machine connected to a domain. The tool is capable of configuring the probe connection via L2TP, PPTP, IPSec, SSTP, or IKEv2 and monitor the events on the monitored machine. You may want to check out some screenshots of Immediate Access in action here. Additional reading Immediate Access: What is Immediate Access? (Update) Immediate Access A Technical/Enumeration Tool Installing Immediate Access: MSDN Article for Immediate Access Immediate Access FAQ: A To paraphrase John Gruber, while Immediate Access claims it is "designed to monitor and report on a machine's ongoing activity on a corporate network", it does not actually do that, or anything like it. The immediate access tool is similar in concept to Netcraft's website scanner. In short, it runs a test to see if any open HTTP(S) port can be reached. No network connection is established at this point, and only if the test fails does the tool move on. When this test fails, the test will continue on some number of (configurable) subsequent retries over a fixed time period. If the test fails at some point, the tool will stop looking, and find an alternate way to stay alive for future runs. If the tool is still not able to establish a connection to your machine, it will simply give up, since the test cannot be made to succeed no matter what you do to your machine. Immediate Access does not send any data back to the server, it just keeps running and running, checking for failed probes. You could see if, for example, the tests fail because you are locked out of the network because you have fallen off the network or there is some other problem with the test itself (I have seen it fail in practice on rare occasions), but in that case it will not report on the network in any way. Q: How to test and
