Phoenix OS V 3.1.1.3.42.A'micromachined metal-on-metal articulating robot's motion control. A micromachined metal-on-metal articulating robot in the micrometer scale has been developed for use as a prototype in a program to construct a micro-robotic manipulator. A model that predicts the performance of this robot in the arm configuration has been developed by numerically simulating its motion using a rigid body simulation technique, and the results are compared to those obtained from the prototype. In the prototype, a voice-coil based actuator is used to achieve the linear translation of the fingertips, and angular motion is controlled by a servo motor. A detailed mechanical design, fabrication process, and a test of the prototype has been performed. A performance model that can predict the achievable speed of the robot with variations in fabrication characteristics has also been developed and a comparison of the performance of the model and the prototype has been performed. The model predicts the attainable speed of the prototype with a significant error of less than 10%, which is acceptable to a laboratory robot. Illumination effects on human vision are a significant contributor to the quality of the resulting images. For example, using flash has historically been one of the primary means for achieving good lighting in a scene. Image sensors may have a limited 'fill factor', where the area of the image sensor that is actually used for sensing the image is relatively small. For example, the area of a CMOS image sensor may be on the order of six percent of the full image height and width. Image sensors are often operated in a single mode at a time, but special light sensitive areas of the sensor may be isolated for improved operation under certain lighting conditions. However, in some circumstances such isolation may lead to lost image information and an inability to accurately sense a scene.
